Dependent Types and Theorem Proving: Introduction to Dependent Types

Wojciech Kołowski

March 2021

General info

- The lectures will be held weekly on Fridays.
- Don't worry if you miss a lecture – the slides are pretty massive and the talks are going to be recorded.
- Each lecture ends with some exercises which will help you familiarize yourself with F* and better understand the ideas covered in the talk.
- But you don't need to do them if you don't want to.
- This talks repo: https://github.com/wkolowski/Dependent-Types-and-Theorem-Proving

Plan of lectures

- Lecture 1: Programming with dependent types.
- Lecture 2: Proving theorems with dependent types.
- Lecture 3: Differences between programming and proving.
- Lecture 4: Examples of bigger programs and longer proofs.
- Lecture 5: A deeper dive into F*.

Learning outcomes

- You won't be scared of all those obscure, scary and mysterious names and notations.
- You will get basic familiarity with the ideas behind dependent types.
- You will begin to see logic and mathematics in a very different light, much closer to your day job (at least if you are a programmer working in F#).
- If you do the exercises, you will gain a basic proficiency in F*.

Introducing F*

- F* (pronounced "eff star") is a general-purpose purely functional programming language.
- Member of the ML family, syntactically most similar to F#.
- Aimed at program verification.
- Dependent types.
- Refinement types.
- Effect system.
- Not a .NET language.
- Neither compiled nor interpreted – it's a proof assistant, i.e. just a typechecker.
- To run a program, it has to be extracted to some other language, like F#, OCaml, C or WASM, and then compiled.

Don't worry, be happy, ask questions

I KNOW YOU DIDN'T UNDERSTAND THE PREVIOUS SLIDE,
BUT BY THE END OF THESE TALKS, YOU WILL!

Useful F* links

- **You can run F* inside your browser** (and have a nice tutorial guide you):
  http://www.fstar-lang.org/tutorial/
- GitHub: https://github.com/FStarLang/FStar
- Homepage: http://www.fstar-lang.org/
- Download: http://www.fstar-lang.org/#download
- Papers (not approachable for ordinary mortals):
  http://www.fstar-lang.org/#papers
- Talks/presentations (more approachable):
  http://www.fstar-lang.org/#talks (some of these are quite approachable if you're interested)

Prerequisites

- To understand what we will be talking about, you should have a working knowledge of F# and the basic concepts of functional programming, namely:
- Functions as first-class citizens, including higher-order functions.
- Algebraic data types, including sum types and product types.
- Pattern matching and recursion.
- Even if you know these, you may be unfamiliar with the particular names – for example, "sum types" is a name used in academia and Haskell, but in F# they are better known as "tagged unions".

Code snippet no 1 - basics of F*

- We will now see some code that shows how these things look in F*.
- See the file Lecture1/Prerequisites.fst.

Values and types

- To understand dependent types, first we have to understand **dependency**.
- And to understand dependency, we need to be aware of the distinction between **values** and **types**.
- By **values**, we mean the bread-and-butter of programming: numbers, strings, arrays, lists, functions, etc.
- It should be pretty obvious to you that in most languages, **types** are not of the same status as numbers or functions.

Dependencies

- Dependency is easy to understand. In fact, if you know basic F#, then you already know most of it, because in F#:
- **Values can depend on values**: we can think that the sum n + m is a number that depends on the numbers n and m. This dependency can be expressed as a function: fun (n m : int) -> n + m.
- **Values can depend on types**: for example, the identity function fun (x : 'a) -> x depends on the type 'a.
- **Types can depend on types**: for example, the F# type Set<'a> depends on the type 'a.

Naming the dependencies

- I bet you spotted the pattern in the previous slide, but it's a good idea to also have a name for the feature provided by each kind of dependency.
- Values can depend on values: (first-class) **functions**.
- Values can depend on types: **polymorphism** (i.e. "generics").
- Types can depend on types: **type operators**.

Dependent types

- There's yet another kind of dependency, which is not present in F#, but is present in F* and is the topic of this lecture.
- **Types can depend on values**: **dependent types**.
- But what are dependent types good for? You have been living your whole life without them, after all!
- Before we go on to explain dependent types, let's see some examples.

Matrix multiplication

- We can only multiply matrices whose dimensions match, i.e. we can multiply an $n \times m$ matrix by a $m \times k$ and get an $n \times k$ matrix as a result.

- How to model this in our favourite programming language without dependent types?

- The best we can do is to have **a type of matrices** Matrix and then matrix multiplication has type matmult : Matrix -> Matrix -> Matrix.

- What happens when we call it with matrices of the wrong dimensions?

- matmult $\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix}$ **is well-typed, but will throw** an

  IllegalArgumentException or some other kind of runtime error, or maybe it will crash even less gracefully.

Matrix multiplication with dependent types

- In a language with dependent types we can create **a type of** $n \times m$ **matrices** `Matrix n m` and give multiplication the type
  ```
  matmult :  (n : ℕ) -> (m : ℕ) -> (k : ℕ) ->
  Matrix n m -> Matrix m k -> Matrix n k
  ```

- Now `matmult` is a function which takes five arguments: the three matrix dimensions and the two matrices themselves.

- After giving it the dimensions of the first matrix from the previous slide, `matmult 2 2` has type `(k : ℕ) -> Matrix 2 2 -> Matrix 2 3 -> Matrix 2 3`.

- It is clear that `matmult 2 2 k` $\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$ $\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix}$ **is not**
  well-typed for any `k`, because the last argument is of type `Matrix 3 3`, but an argument of type `Matrix 2 k` was expected.

A nice paper

- Dependent types can also be used to keep track of units of measure.
- This is possible in F# too, but it's a built-in feature of the compiler, whereas the dependently typed solution is much more principled.
- It is also composable – we can keep track of both matrix dimensions and units.
- There's a nice paper about this: **Type systems for programs respecting dimensions** available at https://fredriknf.com/papers/dimensions2021.pdf

Array access

- When accessing the i-th element of an array, i must be smaller than the length of the array.
- How to model this in our favourite programming language without dependent types?
- We have Array A, **the type of arrays of As**, and we can access its elements with a function get : Array A -> int -> A.
- What happens, when i is greater than the length of the array? Or, what happens when i is negative?
- get [| 'a'; 'b'; 'c'] 5 is well-typed, but will throw an IndexOutOfBoundsException or result in a segmentation fault.

Array access with dependent types 1/2

- In a language with dependent types we can have `Array A n`, **the type of arrays of `A`s whose length is** `n`.
- Then we have a few possibilities to model the type of `get`.
- `get : (n : ℕ) -> Array A n -> (i : ℕ) -> i < n -> A`.
- In this variant, the fourth argument of `get` is a proof that the index isn't out of bounds (we will cover proofs in the next lecture).
- We can't prove `5 < 3`, so we don't have any proof to feed into `get 3 [| 'a'; 'b'; 'c' |] 5 : 5 < 3 -> Char`.

Array access with dependent types 2/2

- get : (n : $\mathbb{N}$) -> Array A n -> (i : $\mathbb{N}\{i < n\}$) ->
  A.
- In this variant we use refinement types (which we will cover
  later today) to automatically guarantee that i isn't out of
  bounds.
- get 3 [| 'a'; 'b'; 'c' |] 5 is not well-typed, because
  the typechecker can't prove 5 < 3, and thus 5 is not of type
  $\mathbb{N}\{5 < 3\}$.

Why should we care?

- Large software systems written in dynamically typed languages are hard to refactor, because all type checks occur at runtime.
- Statically typed languages make the situation better, because they move these checks to compile time, making them much more likely to be useful.
- But in simple functional languages like F# there's still plenty of room for dynamic runtime checks – array bounds checking, division by zero, and a lot of user-defined checks which throw exceptions in case of failure.
- With dependent types, these can be eliminated, which results in **even more refactorability and maintainability**.
- This is also a matter of performance – **no runtime checks means faster programs**.

The running summary 1

- **Dependent types are types that can depend on values**.

We're getting serious

- The above slides present nice fairy tales. . .
- . . . but how do dependent types actually work?
- And how to use them in F*?
- And what can ordinary programmers use them for besides number crunching with matrices and arrays?

Greetings   General idea   **First-class types**   Dependent functions   Dependent pairs and records
00000000   000000000000   ●000000000000   00000   00

What does "first-class" mean?

Juggling dependencies

- Given a functional language like F#, how to enable types to depend on values?

- Of course we want to retain the other kinds of dependencies (values on values, values on types, types on types).

- It turns out it's best **throw away all kinds of dependencies besides the basic one** (values on values)...

- ... and then **turn types into values**!

Greetings   General idea   **First-class types**   Dependent functions   Dependent pairs and records
○○○○○○○○   ○○○○○○○○○○○○○   ○●○○○○○○○○○○○   ○○○○○   ○○

What does "first-class" mean?

Values and types

- So now values encompass both old, ordinary values (integers, tuples, functions, etc.) and new values (types).
- This way we get all four kinds of dependencies:
- Ordinary values can depend on ordinary values.
- Ordinary values can depend on type values.
- Type values can depend on type values.
- Type values can depend on ordinary values.

First-class types

- How do we turn types into values?
- In programming languages' parlance, this process is called **making types first-class citizens of the language**.
- But what does "first-class" mean, anyway?

Greetings | General idea | **First-class types** | Dependent functions | Dependent pairs and records
00000000 | 0000000000000 | 0000000000000 | 00000 | 00

What does "first-class" mean?

What does "first-class" mean?

- In C, we can define functions that take an `int` and return an `int`.
- But we can't define a function that takes a function from `int`s to `int`s and returns an `int`.
- This means that functions from `int`s to `int`s are not treated the same as `int`s.
- As far as C is concerned, we can say that **integers are first-class, but functions are not first-class** (thus, they are "second-class").
- But C has function pointers, so you may be skeptical when I claim it doesn't have first-class functions.

Greetings   General idea   **First-class types**   Dependent functions   Dependent pairs and records
00000000   000000000000   0000●00000000   00000   00

What does "first-class" mean?

Some heuristics

- **The concept of "first-class" is neither precisely defined nor exact**. Rather, it's more of a functional programming folklore that obeys the "I know it when I see it" principle.
- However there are some heuristics that can help you.
- **Something is first-class when it can be**:
- bound/assigned to variables.
- stored in data structures.
- passed to functions as an argument.
- returned from functions.
- constructed at runtime.
- nameless, i.e. it can exist without giving it any name.
- So, which of these is criteria is not fullfilled by C's function pointers?

What does "first-class" mean?

A first-class quiz

- Let's have a little quiz to check if you get it.
- **Are the below language features first-class in F# or not?**
- Functions?
- Recursive functions?
- Arrays?
- Modules?
- Records?
- Types?

Greetings   General idea   **First-class types**   Dependent functions   Dependent pairs and records
00000000   000000000000   0000000●000000   00000   00

What does "first-class" mean?

A type-based definition of "first-class"

- Heuristics from previous slides are nice. . .
- but I prefer to think about first-class-ness in a different way, which is better from the functional programming point of view.
- For a given programming, **a concept X is first-class if there is a type of all Xs**, loosely speaking.
- This means that a language has first-class functions if for any two types A and B there is a type $A \to B$ of all functions from A to B.

Greetings   General idea   **First-class types**   Dependent functions   Dependent pairs and records
00000000   0000000000000   00000000●00000   00000   00

What does "first-class" mean?

A first-class quiz

- Let's have a little quiz to check if you get it.
- **Are the below language features first-class in F# or not?**
- Functions?
- Recursive functions?
- Arrays?
- Modules?
- Records?
- Types?

A first-class quiz answers

- Functions? For any 'a and 'b there's a type of functions 'a -> 'b.
- Recursive functions? There's no separate type of recursive functions, even though there's a syntactic distinction between `let` and `let rec`!
- Arrays? For any type 'a there's a type of arrays, namely `array<'a>`.
- Modules? Modules don't have types, they have signatures. But signatures are not types, so modules are not first-class.
- Records? This one is mixed depending on how you understand it. On the one hand, for any kind of record you can imagine, there's a corresponding type. But on the other hand, there is no type of all record types.
- Types? There are types in F# and there are type variables a', b', c' etc., but we can't assign them any type!

Greetings General idea **First-class types** Dependent functions Dependent pairs and records
00000000 000000000000 000000000●000 00000 00

What does "first-class" mean?

Computing with first-class types

- Previously we learned that "X is first-class" means that there is a type of all Xs.
- For types, this means that we need to have a **type of types**.
- And that's it – we don't need anything else.
- Note: the phrase "types of types" sounds (and looks) bad, so we will call it **the universe of types**, or in short, just **the universe**.
- Because types are first-class in F*, we can assign them to variables, pass them to functions as arguments and return them from functions, and even compute types by recursion.

Code snippet no 2 - first-class types in F*

- It might a bit difficult to wrap your head around the idea of first-class types, so let's see how it plays out in F*.
- The code snippet can be found in
  `Lecture1/FirstClassTypes.fst`

Greetings   General idea   **First-class types**   Dependent functions   Dependent pairs and records
00000000   0000000000000   00000000000●0   00000   00

What does "first-class" mean?

The running summary 2

- Dependent types are types that can depend on values.
- **In dependently typed languages there is a universe – a type whose elements are themselves types**.

Greetings | General idea | **First-class types** | Dependent functions | Dependent pairs and records
00000000 | 000000000000 | 000000000000● | 00000 | 00

What does "first-class" mean?

So far so good

- So far so good, but we still don't know how dependent types work.

- We saw some in the examples, but they were left unexplained.

- We also saw some more in the last code snippet, but those were the crudest and most primitive dependent types in existence.

- **Now that we have learned about first-class types and the universe of types, we can learn dependent types proper**.

Dependent types by analogy

- We will introduce dependent types by analogy.
- **Each of the various kinds of dependent types out there is just a generalization of an ordinary non-dependent type that is well-known to functional programmers**:
- Dependent function types are a generalization of function types.
- Dependent pair types are a generalization of products.
- Dependent record types are a generalization of records.
- Inductive types are a generalization of algebraic data types.

Type families

- In the coming slides, we will often refer to **type families**.
- **A family of types indexed by type** a is just a function a ->
  Type.
- There can be many indices, like in a -> b -> Type.
- We have already seen examples in the last code snippet:
- vec : Type -> nat -> Type is a family of types whose
  members vec A n are lists of length n and elements of type a
- matrix : Type -> nat -> nat -> Type is a family of
  types whose members matrix a n m are $n \times m$ matrices with
  entries of type A.

Non-dependent functions

- Recall how ordinary function types work in F#.
- If a : Type is a type and b : Type is a type, then there is a type a -> b : Type of functions that take an element of a and return an element of b.
- We create functions of type a -> b by writing fun (x : a) -> e where e is an expression of type b in which x may occur.
- If we have a function f : a -> b and x : a, then we we can apply f to x, written f x, to get an element of type b.

Dependent functions

- Now, watch the analogy unfold. . .

- If a : Type is a type and b : a -> Type **is a family of types**, then there is a type (x : a) -> b x **of dependent functions** which take an element of a **named** x and return an element of b x.

- We create functions of type (x : a) -> b x by writing fun (x : a) -> e where e is an expression of type b x in which x may occur.

- If we have a function f : (x : a) -> b x and x : a, then we can apply f to x, written f x, to get an element of type b x.

- Hint: it's probably easiest to pronounce (x : a) -> b x as "for all x of type a, b of x". Thus is revealed the connection to logic, which we will see in the next lecture.

Code snippet no 3 - dependent functions in F*

- Let's see how it works in practice.
- See the code snippet `Lecture1/DependentFunctions.fst`

Greetings   General idea   First-class types   Dependent functions   Dependent pairs and records
00000000   000000000000   000000000000   00000   ●○

Example: everybody loves filling forms

Non-dependent pairs

- Recall how ordinary pairs work in F#.
- If a : Type is a type and b : Type is a type, then there is a type a * b : Type of pairs.
- To create a pair, we write (x, y) where x is of type a and y is of type b.
- To use a pair p : a * b, we use projections – we have fst p : a and snd p : b.
- We can also pattern match on pairs.

Greetings   General idea   First-class types   Dependent functions   Dependent pairs and records
○○○○○○○○   ○○○○○○○○○○○○○   ○○○○○○○○○○○○○   ○○○○○   ○●

Example: everybody loves filling forms

Dependent pairs

- Now, watch the analogy unfold. . .
- If a : Type is a type and b : a -> Type **is a family of types**, then there is **a type** (x : a) * b x : Type **of dependent pairs**.
- To create a dependent pair, we write (x, y) where x is of type a and y **is of type** b x.
- To use a pair p : (x : a) * b x, we use projections – we have fst p : a **and** snd p : b (fst p).
- We can also pattern match on dependent pairs.
